

Theme override model

How a project overrides the look of its site without forking the theme.

Six slides for the working session of the Concordance project.

Deck, minutes and transcript are grouped into one page of the wiki.

The organisation's identity, not the tool's

An integrator wants the name, the logo, the colours and a label here and there.

An integrator never wants to touch the components.

Nothing a reader sees names the tool unless the project asks for it.

theme.yaml

Name, logo, favicon, font families, corner radius.

Light and dark palettes, checked for contrast at build.

Footer text, footer links, an extra stylesheet, label overrides.

Named slots with typed view models

Every page is a set of named slots, each rendered by a component.

The view model of a slot is the contract between the generator and a theme.

A theme that replaces a component keeps the view model; the checks run on the rendered pages.

Hydrate the interactive parts only

One small bundle per island: search, mentions panel, mode switch.

Four cascade layers: tokens, base, components, project.

The project stylesheet is loaded last and wins by construction.

Slots, islands and layers

Named slots with typed view models.

Islands for the interactive parts, content reachable without JavaScript.

A budget of 150 kB per page, measured on every build.
